HAFS-MOM6

Model Configuration

1. Two operational configurations – HFSA and HFSB
2. No differences from HFSA, except the ocean model is MOM6 instead of HYCOM, and some exchange variable differences
3. **No parameter tuning** (yet)
4. ICs and BCs from global RTOFS, the same as the HYCOM in HFSA.

Test cases (19 storms, 542 cases)

2022: Danielle, Earl, Fiona, Gaston, Ian

2021: Elsa, Fred, Grace, Henri, Ida, Larry, Sam

2020: Hanna, Isaias, Laura, Marco, Sally, Teddy, Delta, Zeta

UFS Technical challenge for regional application

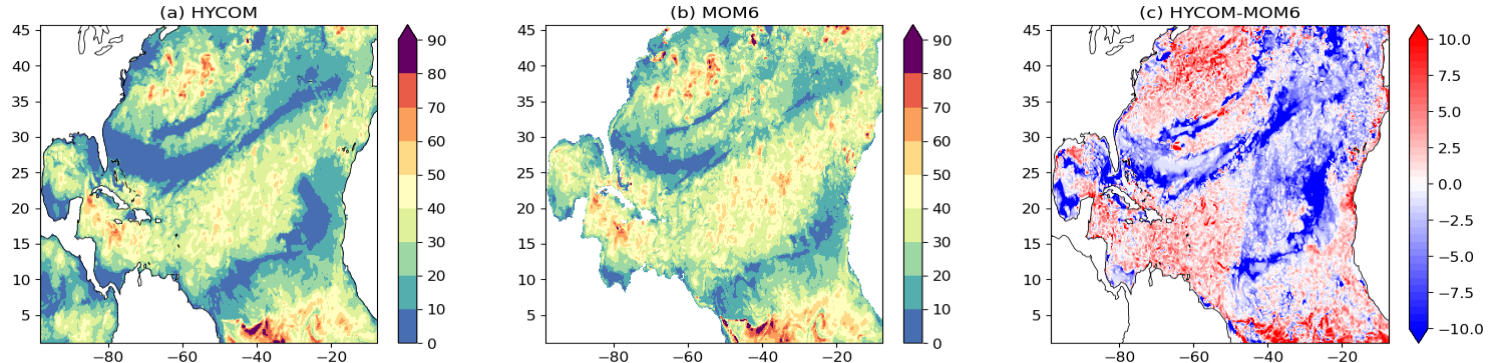

$$\text{merged flux} = \text{flux}^{\text{fv3}} * \delta + \text{flux}^{\text{cdep}} * (1 - \delta)$$

where $\delta = 1$ in overlapped regions
 $\delta = 0$ in non-overlapped regions

Mixed Layer Depth (MLD) after 96 hour integration

Hurricane Laura (2020): forecast hour 96 valid at 2020082900

Concluding remarks

HFSA is insensitive to an ocean model component, where tests are done for HYCOM vs MOM6. Noted is that both the systems use the same ocean IC.

However, the TC structures are different, especially thermal properties. There is significant T anomalies for HFSA-HYCOM exhibiting significant contrast in the anomaly, and warming at higher altitude, relative to the counterpart HFSA-MOM6.

To support this finding, extended analysis is in progress.

UFS's regional application challenge:

Treatment for state variables to cover non-overlapped areas for the FV3 and MOM6 domains.
